

TITLE OF THE INVENTION  
CAMERA SYSTEM, CAMERA, ACCESSORY DEVICE AND METHOD FOR  
JUDGING AND CONTROLLING AN ACCESSORY DEVICE

CROSS-REFERENCE TO RELATED APPLICATIONS

5           This is a Continuation-in-Part application of U.S.  
Patent Application No. 10/352,621, filed January 28,  
2003, the entire contents of which are incorporated  
herein by reference.

10           This application is based upon and claims the  
benefit of priority from the prior Japanese Patent  
Applications No. 2002-024485, filed January 31, 2002;  
No. 2002-024486, filed January 31, 2002;  
No. 2002-024566, filed January 31, 2002; and  
No. 2002-200213, filed July 9, 2002, the entire  
15           contents of all of which are incorporated herein by  
reference.

BACKGROUND OF THE INVENTION

1. Field of the Invention

20           The present invention relates to a camera system  
comprising a camera body and camera accessories such as  
interchangeable lenses, to a camera body and accessory  
devices applicable to such a camera system and also to  
a method of judging and controlling an accessory  
device.

25           2. Description of the Related Art

Generally, camera accessories including an  
interchangeable lens and a flash unit are releasably

10/616,314

arranged in the camera body.

When such a camera accessory is mounted on the camera body, they communicate with each other. It becomes possible to exploit the accessory mounted on the camera body maximally for performance as a result of the communication. In other words, if the accessory is adapted to the camera body on which it is mounted, the accessory can be exploited optimally for performance.

As related art in this field of technology, Japanese Patent Application KOKAI Publication No. 1-221728 discloses a camera with which a number of interchangeable lenses can selectively be used, wherein each of the interchangeable lenses is provided with a memory means for storing identification data and lens category data of the group of lenses to which it belongs. The camera body is adapted to appropriately control the lens that is mounted on it according to the data stored in the lens.

#### BRIEF SUMMARY OF THE INVENTION

In the first feature of the present invention, there is providing a camera system including a camera body and an accessory device to be releasably mounted on the camera body, the system comprising:

a camera side identification data table held by the camera body;

an accessory device side identification data table

held by the accessory device and congruous with the camera side identification data table;

5 a specifying section arranged in the camera body to specify an appropriate data address to the accessory device;

10 a transmitting section arranged in the accessory device to transmit identification data stored in the accessory device side identification data table at the data address specified by the specifying section to the camera body; and

15 a judging section arranged in the camera body to determine if a dedicated accessory is mounted or not by comparing the identification data transmitted back from the accessory device and the identification data stored in the camera side identification data table at the address corresponding to the data address.

20 In the second feature of the invention, there is provided an accessory device to be releasably mounted on a camera body having a functional feature of determining if an accessory device designed to be dedicated to the camera body is mounted on it or not, the accessory device comprising:

25 an identification data table held congruous with the camera side identification data table provided in the camera body; and

a transmitting section that selects identification data in the identification data table and transmits it

to the camera body in response to a specification by the camera body.

In the third feature of the invention, there is provided a camera body having a functional feature of  
5 determining if an accessory device designed to be dedicated to it is mounted on it or not, the camera body comprising:

an identification data table congruous with the accessory device side identification data table held by  
10 the accessory device;

a specifying section that specifies an appropriate data address to the accessory device; and

a judging section that determines if the dedicated accessory device is mounted on it or not by comparing  
15 the identification data corresponding to the specified data address of the accessory device side identification data table and transmitted back from the accessory device according to the specification by the specifying section and the identification data stored  
20 in the camera side identification data table and corresponding to the address.

In the fourth feature of the invention, there is provided a camera system including a camera body and an accessory device to be releasably mounted on the camera  
25 body, the system comprising:

a camera side memory section arranged in the camera body to store identification data congruous with

the identification data stored in the accessory device;

an accessory device side memory section arranged in the accessory device to store identification data congruous with the identification data stored in the camera body;

a detecting section that detects a predetermined operation by the user;

a comparing section arranged in the camera body to receive the identification data from the accessory device in response to the detection by the detecting section of a predetermined operation and compare the identification data with the corresponding camera side identification data; and

a judging section that judges if the dedicated accessory device is mounted on the camera body according to the result of the comparison by the comparing section.

In the fifth feature of the invention, there is provided a camera system of a combination of a camera body and an accessory device, the camera system comprising:

a communicating section arranged in the camera body to communicate with a specific accessory device according to a predetermined communication protocol;

a discriminating section arranged in the camera body to determine if the accessory device coupled to it holds a predetermined quantity indicating a state of a

pre-selected electric phenomenon; and

5 a holding section arranged in the accessory device to hold the predetermined quantity indicating the state of the pre-selected electric phenomenon in a form recognizable to the discriminating section in the camera body.

10 In the sixth feature of the invention, there is provided a camera body applicable to a camera system of a combination of a camera body and an accessory device, the camera body comprising:

a communicating section that communicates with a specific accessory device according to a predetermined communication protocol; and

15 a discriminating section that determines if the accessory device coupled to it holds a predetermined quantity indicating a state of a pre-selected electric phenomenon or not.

20 In the seventh feature of the invention, there is provided a camera system including a camera body and a camera accessory to be releasably mounted on the camera body, the system comprising:

a camera side arithmetic section arranged in the camera body to store an arithmetic expression to be used for performing predetermined arithmetic operation;

25 an accessory side arithmetic section arranged in the accessory to store an arithmetic expression congruous with the arithmetic expression of the camera

side arithmetic section;

an arithmetic operation data outputting section  
arranged in the camera body to output arithmetic  
operation data common to the camera side arithmetic  
5 section and the accessory side arithmetic section;

a judging section arranged in the camera body to  
compare the outcome of the arithmetic operation  
performed by the camera side arithmetic section and  
that of the arithmetic operation performed by the  
10 accessory side arithmetic section and judge that the  
right accessory is mounted on the camera body when the  
outcomes agree with each other.

In the eighth feature of the invention, there is  
provided a camera to which an accessory to be  
15 releasably mounted, the camera comprising:

a camera side arithmetic section that stores an  
arithmetic expression congruous with the arithmetic  
expression stored in an accessory side arithmetic  
section possessed by the accessory;

20 an arithmetic operation data outputting section  
that outputs arithmetic operation data to the accessory  
side arithmetic section and the camera side arithmetic  
section;

a judging section that receives an outcome of the  
25 arithmetic operation of the camera side arithmetic  
section and that of the arithmetic operation of the  
accessory side arithmetic section and judges if the

accessory is the right accessory or not by comparing the outcomes.

In the ninth feature of the invention, there is provided a judgment control method to be used by an  
5 accessory that is releasably mounted on a camera body, the method comprising:

receiving at the accessory side a plurality of numerical value data from the camera body;

selecting a data to be used for an arithmetic  
10 operation for judgment control of the accessory out of the plurality of numerical value data;

performing the arithmetic operation for judgment control of the accessory, using the selected data; and

transmitting the outcome of the arithmetic  
15 operation for judgment control to the camera body.

Additional features and advantages of the invention will be set forth in the description which follows, and in part will be obvious from the description, or may be learned by practice of the  
20 invention. The features and advantages of the invention may be realized and obtained by means of the instrumentalities and combinations particularly pointed out hereinafter.

#### BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

25 The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate presently preferred embodiments of the

invention and, together with the general description given above and the detailed description of the preferred embodiments given below, serve to explain the principles of the invention.

5           FIG. 1 is a functional block diagram of the first embodiment of camera system according to the invention, illustrating its configuration on the basis of signal flow;

10           FIG. 2 is a schematic illustration of identification data tables that may be stored in the identification data storage section 16 and the identification data storage section 104 of FIG. 1;

15           FIG. 3 is a flow chart of the operation of the camera body 10 of the first embodiment of camera system according to the invention;

            FIG. 4 is a flow chart of the operation of the interchangeable lens 100 of the first embodiment of camera system according to the invention;

20           FIG. 5 is a block diagram of the second embodiment of camera system according to the invention, illustrating its configuration;

25           FIG. 6 is a block diagram of the second embodiment of the invention, illustrating an example of arrangement that is adapted to detect and determine an electric current value as hardware-related information;

            FIG. 7 is a block diagram of the second embodiment of the invention, illustrating an example of

arrangement that is adapted to detect and determine a voltage value as hardware-related information;

FIG. 8 is a block diagram of the second embodiment of the invention, illustrating another example of arrangement that is adapted to detect and determine an  
5 electric current value as hardware-related information;

FIG. 9 is a block diagram of the second embodiment of the invention, illustrating another example of arrangement that is adapted to detect and determine  
10 a voltage value as hardware-related information;

FIG. 10 is a block diagram of the second embodiment of the invention, illustrating still another example of arrangement that is adapted to detect and determine an electric current value as hardware-related  
15 information;

FIG. 11 is a block diagram of the second embodiment of the invention, illustrating still another example of arrangement that is adapted to detect and determine a voltage value as hardware-related  
20 information;

FIG. 12 is a flow chart of the operation of the camera body of the second embodiment of the invention;

FIG. 13 is a flow chart of the operation of the interchangeable lens of the second embodiment of the  
25 invention;

FIG. 14 is a functional block diagram of the third embodiment of the invention, which is a camera system,

formed on the basis of the flow of signals to  
illustrate its configuration;

FIG. 15 is a schematic illustration of the table  
format of data to be used for arithmetic operations in  
5 the third embodiment of the invention;

FIG. 16 is a schematic block diagram of a single-  
lens reflex camera with interchangeable lenses realized  
by applying the present invention;

FIG. 17 is a flow chart illustrating the sequence  
10 of operation of the camera body 180 of the camera of  
FIG. 16;

FIG. 18 is a functional block diagram of the  
fourth embodiment of the invention, which is a camera  
system, formed on the basis of the flow of signals to  
15 illustrate its configuration; and

FIG. 19 is a schematic illustration of the table  
format of data to be used for arithmetic operations in  
the fourth embodiment of the invention.

#### DETAILED DESCRIPTION OF THE INVENTION

20 Now, preferred embodiments of the present  
invention will be described by referring to the  
accompanying drawing.

FIG. 1 is a functional block diagram of the first  
embodiment of camera system according to the invention,  
25 illustrating its configuration in terms of signal flow.

Referring to FIG. 1, the camera system comprises  
a camera body 10 and an interchangeable lens 100, which

is a camera accessory releasably mounted on the camera body 10.

5       The camera body 10 includes a communicating section 12 to be used for data communication with the interchangeable lens 100, an identification data selecting section 14, an identification data storage section 16, an identification data judging section 18, a control section 20 and a lens mounting/releasing switch (SW) 22.

10       On the other hand, the interchangeable lens 100 is releasably mounted on the camera body 10 and includes a communicating section 102 for communicating with the camera body 10 and an identification data storage section 104.

15       The communicating section 12 communicates with the interchangeable lens 100. As will be described in detail, it transmits a group number and an address as identification data necessary for identifying the interchangeable lens 100 and receives identification data corresponding to the group number and the address from the interchangeable lens 100.

20       The identification data selecting section 14 is adapted to select the group number and the address as identification data. The identification data storage section 16 sorts out identification data by way of group numbers and addresses and stores them.

25       The identification data judging section 18 is

adapted to compare the identification data relating  
to a group number and an address and input from the  
communicating section 12 and the identification data  
relating to a group number and an address and read out  
5 from the identification data storage section 16 and  
determine if they agree with each other or not.

The first matching determining means comprises  
the identification data selecting section 14,  
the identification data storage section 16 and  
10 the identification data judging section 18.

The lens mounting/releasing switch 22 is a switch  
for detecting if the interchangeable lens 100 is  
mounted on the camera body 10 or not.

The control section 20 allows the camera to  
15 operate properly when a matching interchangeable lens  
100 is coupled to the camera body or prohibits the  
latter from operating when an interchangeable lens 100  
that is not matching the camera body is coupled to the  
latter in response to the result of the detection of  
20 the lens mounting/releasing switch 22 and that of the  
judgment of the identification data judging section 18.

Note that, the control section 20 comprehensively  
controls only the camera body 10 when an inter-  
changeable lens 100 is not coupled to the camera body  
25 10, whereas it comprehensively controls the entire  
camera system including an interchangeable lens 100  
when the latter matches and is coupled to the camera

body 10.

The communicating section 102 of the interchangeable lens 100 operates to read the identification data corresponding to the group number and the address  
5 received from the communicating section 12 of the camera body 10 out of the identification data storage section 104 and transmits it back to the communicating section 12 of the camera body 10.

The identification data storage section 104 sorts  
10 out identification data by way of group numbers and addresses and stores them.

Both the identification data storage section 16 of the camera body 10 and the identification data storage section 104 of the interchangeable lens 100 store  
15 identification data that are common to the camera body 10 and the interchangeable lens 100 and hence same and identical. An identification data is produced by using a plurality of identification data tables. For example, an identification data may be produced by  
20 using three random identification data tables as shown in FIG. 2.

FIG. 2 is a schematic illustration of identification data tables. As described above, the identification data stored in the identification data storage section 16 and the corresponding data stored in  
25 the identification data storage section 104 are sorted into groups according to group numbers including

Group 1, Group 2, Group 3 and so on. Additionally,  
the data are stored in the two-dimensional regions of  
each of the groups and the two-dimensional regions are  
defined, for instance, by horizontal Addresses X and  
5 vertical Addresses Y. Thus, the tables look like code  
tables.

In the instance of FIG. 2, the values of vertical  
Addresses Y are found within a range between 1 and 4.  
Similarly, the values of horizontal Addresses X are  
10 found within a range between 1 and 4. Thus the  
identification data is stored at  $4 \times 4 = 16$  addresses  
that are expressed by combinations of vertical and  
horizontal Addresses (X, Y).

For example, if "1" is specified for Group (out  
15 of Group 1, Group 2 and Group 3 in FIG. 2) of the  
identification data tables and "2" and "2" are  
specified respectively for Address X and Address Y, an  
identification data of "5" is defined. The identifi-  
cation data selecting section 14 specifies (selects)  
20 the group number of the identification data tables and  
Addresses (X, Y).

The data defined by means of the specified group  
number and address is then sent to the identification  
data judging section 18. As described above, the  
25 identification data judging section 18 judges if the  
data selected in a manner as described above and stored  
in the identification data storage section 16 and the

data stored in the identification data storage section 104 of the interchangeable lens 100 and transmitted to it by way of the communicating sections 102 and 12 agree with each other or not.

5           Note again that the identification data stored in the identification data storage section 104 of the interchangeable lens 100 is selected by using the group number and the addresses selected by the identification data selecting section 14 of the camera body 10.

10           The control section 20 controls the operation of the camera according to the judgment of the identification data judging section 18. The control section 20 is coupled to the lens mounting/releasing switch (SW) 22 for detecting if the interchangeable  
15           lens 100 is mounted or released. Thus, the control section 20 is notified of the timing at which the interchangeable lens 100 is mounted or released.

          Now, the operation of selecting an identification data stored in the identification data storage section  
20           16 will be described below.

          For the operation of selecting an identification data, the group number and the addresses are sequentially incremented. For example, if "1" is specified for Group of the identification data tables  
25           and "1" and "1" are specified respectively for Address X and Address Y for the first round, "2" is specified for Group and "2" and "2" are specified respectively

for Address X and Address Y, although an identification data may be selected in a different way as will be discussed below.

5 First, an identification data may be switched to another as a function of time. For example, the groups and the addresses of the identification data tables may be switched to other ones every day.

10 Second, an identification data may be switched to another as a function of the data stored in the interchangeable lens 100. For example, an identification data may be selected by referring to the number specifically allocated to the lens or to the type of the lens.

15 Third, an identification data may be switched to another as a function of the data stored in the camera body 10. For instance, the data may be stored when the camera body is manufactured.

20 Fourth, an identification data may be selected by using a random number. It may be so arranged that the camera body 10 generates a random number each time the camera is operated and transmits the random number to the interchangeable lens 100.

25 Of the above described identification data storage section 16 and the identification data storage section 104, a writable memory may be used at least for the identification data storage section 104.

Now, the processing operation of the above

described embodiment of camera system will be described by referring to the flow charts of FIGS. 3 and 4.

5 Firstly, the processing operation of the camera body 10 will be described by referring to the main flow chart of the camera body 10.

As the camera body 10 is powered typically by means of a battery (not shown) to start the sequence of the processing operation. Firstly, the camera system is initialized for operation in Step S1. The  
10 initialization may include selection of a port. Then, in Step S2, it is determined if an interchangeable lens 100 is mounted on the camera body 10 or not according to the result of the detecting operation of the lens mounting/releasing switch 22.

15 If it is determined in Step S2 that an interchangeable lens 100 is not mounted on the camera body 10, the processing operation proceeds to Step S3, in which a process without a lens is conducted. Subsequently, the processing operation goes back to  
20 Step S2. If, on the other hand, it is determined in Step S2 that an interchangeable lens 100 is mounted, the processing operation proceeds to Step S4.

In Step S4, it is determined if the interchangeable lens 100 is newly mounted on the camera body 10  
25 (in other words changed) or it has been mounted for sometime. If it is determined that the interchangeable lens 100 is newly mounted, a specific processing

operation of identifying the lens is conducted in steps starting from Step S5. If, on the other hand, it is determined that the interchangeable lens 100 has been mounted for sometime, the processing operation proceeds  
5 to Step S14.

In Step S5, an identification data is selected. More specifically, an identification data stored in the identification data storage section 16 is selected by the identification data selecting section 14 in  
10 the camera body 10. To do this, a group number and an address data are specified by means of the identification data tables as shown in FIG. 2.

Subsequently, in Step S6, the group number of the identification data selected in Step S5 is transmitted  
15 from the camera body 10 to the interchangeable lens 100. This step, or Step S6, corresponds to Step S24 in the flow chart of FIG. 4, which will be described in detail hereinafter.

Then, in Step S7, Addresses X and Y of the  
20 identification data selected in Step S5 are transmitted from the camera body 10 to the interchangeable lens 100 similarly to Step S6. Again, this step, or Step S7, corresponds to Step S25 in the flow chart of FIG. 4, which will also be described in detail hereinafter.

25 Thereafter, in Step S8, the identification data transmitted from the interchangeable lens 100 in response to the above described identification data

transmitted in Steps S6 and S7 is received by the camera body 10. Then, the received identification data is judged in Step S9. More specifically, the identification data stored in the identification data storage section 16 of the camera body 10 is compared with the identification data transmitted from the interchangeable lens 100 in Step S8.

In Step S10, it is determined if the two identification data agree with each other or not. If the identification data do not agree with each other, the processing operation proceeds to Step S11, where the interchangeable lens 100 is judged to be no good (NG). Then, any subsequent operation for driving the camera is prohibited in Step S12. Subsequently, the processing operation proceeds to Step S13, where a damage processing operation is conducted so as to make the camera system reject any user operation.

If, on the other hand, it is determined in Step S10 that the identification data agree with each other, the processing operation proceeds to Step S14, where the interchangeable lens 100 is judged to be OK. Then, the camera system is driven to operate properly in Step S15.

Then, in Step S16, it is determined if the interchangeable lens 100 is released or not. The processing operation goes back to Step S2 when it is determined that the interchangeable lens 100 is released, whereas

the processing operation proceeds to Step S17 when it is determined that the interchangeable lens 100 is not released.

5 In Step S17, it is determined if the operation of identifying the interchangeable lens 100 is to be conducted or not. This operation of identifying the lens will be conducted in response to a user's manual operation of turning on the power switch, the release switch or the like.

10 If it is determined that the operation of identifying the lens is to be conducted, the processing operation moves to Step S5 and the succeeding steps are followed. If, on the other hand, it is determined that the operation of identifying the lens is not to be  
15 conducted, the processing operation goes to Step S15 to follow the procedure of the normal processing operation. Thereafter, the processing operation proceeds to Step S16 and the ordinary processing loop is repeatedly followed except when the processing  
20 operation for releasing the lens or that of checking the lens is conducted in Step S16 or S17, whichever appropriate.

Now, the processing operation of the interchangeable lens 100 will be described by referring  
25 to the main flow chart of the interchangeable lens 100 as shown in FIG. 4.

In this sequence, firstly, the interchangeable

lens 100 is initialized for operation in Step S21.  
The initialization may typically include selection of  
a port. Then, a communication check is conducted in  
Step S22. A communication check is an operation of  
5 the communicating section 102 in the interchangeable  
lens 100 for checking if there is a request for  
communication issued from the camera body 10 or not.  
The processing operation proceeds to Step S28 when  
there is no request for communication, whereas it  
10 proceeds to Step S23 when there is a request for  
communication.

Then, in Step S23, it is determined if there is  
a transmission for identification data or not. If it  
is determined in Step S23 that there is no transmission  
15 for identification data, the processing operation  
proceeds to Step S28. If, on the other hand, it is  
determined in Step S23 that there is a transmission for  
identification data, the processing operation proceeds  
to Step S24.

20 In Step S24, the group number of the identifica-  
tion data transmitted from the camera body 10 in  
Step S6 of the flow chart of FIG. 3 is recognized  
by the interchangeable lens 100. Similarly, in  
Step S25, Addresses X and Y of the identification  
25 data transmitted from the camera body 10 in Step S7 of  
the flow chart of FIG. 3 is recognized by the  
interchangeable lens 100.

Then, in Step S26, an identification data stored in the identification data storage section 104 in the interchangeable lens 100 is selected by means of the above described group number and Addresses X and Y.

5      Thereafter, in Step S27, the identification data selected in Step S26 is transmitted back from the interchangeable lens 100 to the camera body 10.

Subsequently, in Step S28, the ordinary processing operation of the interchangeable lens 100 is conducted.

10      Then, in Step S29, it is determined if there is a communication or not. If it is determined that there is a communication, the processing operation proceeds to Step S23 for the above described operation of communication check. If, on the other hand, it is  
15      determined that there is no communication, the processing operation proceeds to Step S28 for the ordinary processing loop.

While any subsequent operation for driving the camera is prohibited when the lens is judged to be NG  
20      in Steps S11 and S12 in the flow chart of FIG. 3 in the above description of the embodiment, the embodiment is by no means limited to such an arrangement. For example, it may alternatively be so arranged that the fact that the lens is NG is notified instead of  
25      prohibiting the operation of driving the camera. Still alternatively, the normal procedure of the processing operation may be followed, while limiting the use of

some of the functional features.

The damage processing operation in Step S13 of the flow chart of FIG. 3 may be a halt of the operation of the interchangeable lens 100.

5           While both the identification data storage section 16 of the camera body 10 and the identification data storage section 104 of the interchangeable lens 100 store identification data that are common to the camera body 10 and the interchangeable lens 100 and hence  
10           same and identical in the above description of the embodiment, the identification data stored in the storage sections may not necessarily be so if the identification data stored in the identification data storage section 104 of the interchangeable lens 100 at  
15           least include the identification data stored in the identification data storage section 16 of the camera body 10.

          While the camera accessory that can be releasably mounted on the camera body 10 is an interchangeable  
20           lens 100 in the above description of the embodiment, the interchangeable accessory may alternatively be a flash unit, a battery pack or something else.

          While the identification data of the camera body 10 and that of the interchangeable lens 100 are  
25           collated (to recognize the lens) when the lens is changed in the above description of the first embodiment, it may alternatively be so arranged that

the user can select the timing for collating the two identification data.

As described above, it is now possible to determine if the camera accessory mounted on the camera body of the first embodiment of the present invention is one that is designed so as to be dedicated to the camera body or not.

Now, the second embodiment of the invention will be described below.

The second embodiment is a camera system comprising a camera body and an interchangeable lens, in which the proper applicability of the interchangeable lens to the camera body can be precisely determined. The second embodiment is also designed to provide a camera body and an interchangeable lens that are applicable to the camera system.

FIG. 5 is a block diagram of the second embodiment of camera system according to the invention, illustrating its configuration. The components similar or identical to those of the first embodiment are designated at the same reference numerals and will not be described in detail.

The camera system comprises a camera body 30 and an interchangeable lens 110 that can be releasably mounted on the camera body 30 by way of a lens mount or the like.

The camera body 30 includes a communicating

section 12, an identification data selecting section  
14, an identification data storage section 16,  
an identification data judging section 18, a control  
section 20, a lens mounting/releasing switch (SW) 22  
5 and a hardware-related information judging section 32.

On the other hand, the interchangeable lens 110 is  
releasably mounted on the camera body 30 and includes  
a communicating section 102 for communicating with  
the camera body 30, an identification data storage  
10 section 104 and a hardware-related information output  
section 112.

The hardware-related information judging section  
32 is means for judging the hardware-related  
information output from the interchangeable lens 110  
15 when the interchangeable lens 110 is mounted on the  
camera body 30. It operates as second matching  
determining means. The control section 20 allows  
the camera to operate properly when a matching  
interchangeable lens 110 is connected to the camera  
20 body or prohibits the latter from operating when  
an interchangeable lens 110 that is not matching the  
camera body is connected to the latter in response to  
the result of the judgment of the hardware-related  
information judging section 32, that of the detection  
25 of the lens mounting/releasing switch 22 and that  
of the judgment of the identification data judging  
section 18.

The hardware-related information output section 112 is designed to operate as state-indicating quantity holding means that is adapted to output hardware-related information to the hardware-related information judging section 32 of the camera body 30.

The hardware-related information is output as quantity indicating the state of the electric phenomenon selected to maintain a specific relationship with an attribute of the interchangeable lens 110.

10 The attribute of the interchangeable lens 110 may be its focal length, a physical quantity that is provided in advance in it and can be used to identify it, or its product number.

The quantity indicating the state of the electric phenomenon may be an electric current value, a voltage value, an electric resistance value, an electric capacitance value, a frequency value or the duty factor of an electric value that changes cyclically.

Now, the arrangement for judging hardware-related information will be described by referring to FIGS. 6 through 9.

FIG. 6 is a block diagram illustrating an example of arrangement that is adapted to detect and determine an electric current value as hardware-related information.

The interchangeable lens 110 comprises a lens microcomputer 114 that includes a communicating section

102 and an identification data storage section 104 and a constant current source 116 that corresponds to the hardware-related information output means 112 and operates as state-indicating quantity holding means.

5 The constant current source 116 is adapted to output a constant current I showing a value that corresponds to the attribute of the interchangeable lens 110.

More specifically, the constant current source 116 outputs a constant electric current I that  
10 represents the type of the interchangeable lens, e. g., the 28 - 105 mm zoom lens or the 100 mm macro-lens or the ID number or the product number (or part of the number) of the interchangeable lens that is stored in the EEPROM or the like (not shown) at the time when the  
15 interchangeable lens is manufactured.

On the other hand, the camera body 30 comprises an electric current detecting section 34 that operates as second matching determining means and corresponds to the hardware-related information judging section 32 and  
20 a body microcomputer 36 that includes the communicating section 12, identification data selecting section 14, identification data storage section 16, identification data judging section 18 and control section 20.

The electric current detecting section 34 is  
25 adapted to detect the value of the constant electric current I output from the constant current source 116 and output the detected value. The body microcomputer

36 determines if the connected interchangeable lens 110 matches the camera body on the basis of the electric current value detected by the electric current detecting section 34 and, if it is determined that the interchangeable lens 110 matches the camera body, it also operates as communicating means, coding means and first matching determining means so as to determine the attribute of the interchangeable lens 110 and perform a control operation suited for the interchangeable lens 110 on the basis of the determined attribute.

The body microcomputer 36 has a data base that is necessary for the attribute of the matching interchangeable lens 110. Additionally, the body microcomputer 36 determines if the electric current value detected by the electric current detecting section 34 agrees with one of the electric current values stored in the data base or not and then if the connected interchangeable 110 is a matching lens or not on the basis of agreement or disagreement. Furthermore, the body microcomputer 36 determines the attribute of the connected interchangeable lens 110 by collating the electric current value with the values stored in the data base.

FIG. 7 is a block diagram illustrating an example of arrangement that is adapted to detect and determine a voltage value as hardware-related information.

The interchangeable lens 120 comprises a constant

voltage circuit 122 in place of the constant current source 116 of FIG. 6. The constant voltage circuit 122 outputs a constant voltage V showing a voltage value that represents its own attribute. It corresponds to  
5 the hardware-related information output section 112 and operates as state-indicating quantity holding means.

On the other hand, the camera body 40 comprises a voltage detecting section 42 in place of the electric current detecting section 34 of FIG. 6. The voltage  
10 detecting section 42 is adapted to detect the value of the constant voltage V output from the constant voltage circuit 122 and output the detected value. It corresponds to the hardware-related information judging section 32 and operate as second matching  
15 determining means.

Since the arrangement of FIG. 7 is identical with that of FIG. 6 except that a voltage value is detected as hardware-related information. It will not be described any further.

20 FIG. 8 is a block diagram illustrating another example of arrangement that is adapted to detect and determine an electric current value as hardware-related information.

The interchangeable lens 110 of FIG. 8 is same as  
25 the one illustrated in FIG. 6.

On the other hand, the camera body 50 comprises a resistor 52 and a body microcomputer 54 in place of

the electric current detecting section 34 and the body microcomputer 36 of FIG. 6.

5       The resistor 52 has a resistance value R and operates as part of the second matching determining means arranged on the input line of the constant electric current I output from the constant current source 116 and between the constant current source 116 and the ground. The body microcomputer 54 has an A/D converter 56 in the inside thereof that operates as  
10       second matching determining means for detecting the voltage value  $V = I \times R$  produced by the resistor 52 and converting the detected voltage into a digital data. Since the arrangement of FIG. 8 is otherwise identical with that of FIG. 6, it will not be described any  
15       further.

FIG. 9 is a block diagram illustrating another example of arrangement that is adapted to detect and determine a voltage value as hardware-related information.

20       The interchangeable lens 120 of FIG. 9 is same as the one illustrated in FIG. 7.

On the other hand, the camera body 60 comprises a body microcomputer 54 that includes an A/D converter 56 similar to the one described above by referring to  
25       FIG. 8 but does not comprise any voltage detecting section 42 described above by referring to FIG. 7. Since the arrangement of FIG. 9 is otherwise identical

with that of FIG. 7, it will not be described any further.

FIG. 10 is a block diagram illustrating still another example of arrangement that is adapted to  
5 detect and determine an electric current value as hardware-related information.

With the arrangement of FIG. 10, hardware-related information is used only to detect if the interchangeable lens 130 matches the camera body 50. In other  
10 words, it is not used to detect the focal length or some other attribute of the interchangeable lens 130.

The body microcomputer 54 has a coding section (not shown) in the inside thereof. It prepares a command for indicating the electric current value  
15 output from the interchangeable lens 130 connected to it and encodes the command by means of the coding section. Then, it transmits the coded command to the lens microcomputer 114 of the interchangeable lens 130.

The lens microcomputer 114 of the interchangeable  
20 lens 130 has a decoding section (not shown) in the inside thereof (the decoding section is included in the communicating section 102 if the interchangeable lens has a configuration corresponding to that of FIG. 5). Thus, it decodes the coded command it receives from the  
25 body microcomputer 54 and sets the electric current I output from the constant current source 116 to a value specified by the decoded command. In other words, the

constant current source 116 of the interchangeable lens 130 is variable.

Since the arrangement of FIG. 10 is otherwise identical with that of FIG. 8, it will not be described  
5 any further.

With the above described arrangement, the body microcomputer 54 detects the electric current value of the electric current I output from the interchangeable lens 130. If the interchangeable lens 130 is a  
10 matching one or not is determined depending on if the detected electric current value agrees with the one specified by the body microcomputer 54 by way of the command it issued.

In other words, for the interchangeable lens 130  
15 to prove that it matches the camera body 50, the interchangeable lens 130 has to have a decoding section that corresponds to the coding section of the camera body 50 and a means for outputting the electric current value of the electric current I that corresponds to the  
20 command from the camera body 50.

FIG. 11 is a block diagram illustrating still another example of arrangement that is adapted to detect and determine a voltage value as hardware-related information.

25 In this example, as in the case of the example of FIG. 10, hardware-related information is used only to detect if the interchangeable lens 140 matches the

camera body 60. In other words, it is not used to detect the focal length or some other attribute of the interchangeable lens 140.

5       The body microcomputer 54 has a coding section (not shown) in the inside thereof. It prepares a command for indicating the voltage value output from the interchangeable lens 140 connected to it and encodes the command by means of the coding section. Then, it transmits the coded command to the lens  
10       microcomputer 114 of the interchangeable lens 140.

      The interchangeable lens 140 has a decoding section (not shown) in the inside thereof. Thus, it decodes the coded command it receives from the body microcomputer 54 and sets the voltage V output from the  
15       constant voltage circuit 122 to a value specified by the decoded command. In other words, the constant voltage circuit 122 of the interchangeable lens 140 is variable.

      The arrangement of FIG. 11 is identical to that of  
20       FIG. 6 in any other aspects. The body microcomputer 54 determines the applicability of the interchangeable lens 140 in the same way as in the case explained with reference to FIG. 10. The process of determining the applicability will not be described.

25       The communication including encoding and decoding performed in the second embodiment may be realized by using such identification data utilized in the first

embodiment.

Now, the operation of the camera body 30 of the second embodiment will be described by referring to the flowchart of FIG. 12.

5           As the camera system is operated, it is initialized in Step S31. The initialization includes checks of components and selections of initial values for them. Then, in Step S32, it is determined if an interchangeable lens 110 is mounted on the camera  
10           body 30 or not according to the result of the detecting operation of the lens mounting/releasing switch 22. In Step S33, it is determined if an interchangeable lens 110 is newly mounted on the camera body 30 or not according to the result of the detecting operation.

15           If it is determined that the interchangeable lens 110 is newly mounted on the camera body 30, it is confirmed if the interchangeable lens 110 is a matching lens or not by means of a communication protocol as described below before starting communications and  
20           other operations.

          If it is determined that an interchangeable lens 110 is newly mounted on the camera body 30, the processing operation proceeds to Step S34, where a group number and Addresses X and Y are specified to  
25           select an identification data typically by generating random numbers.

          Then, in Step S35, the group number of the

identification data is transmitted to the communicating section 102 of the interchangeable lens 110 by way of the communicating section 12. Thereafter, in Step S36, Addresses X and Y of the identification data are  
5 transmitted. In the next step of S37, the camera body 30 waits for the identification data transmitted back from the interchangeable lens 110 and, as the identification data is transmitted back, it is received by way of the communicating section 12 in Step S38.

10 Then, in Step S39, the identification data judging section 18 compares the identification data including the group number and Addresses X and Y and read out from the identification data storage section 16 and the identification data received from the interchangeable  
15 lens 110. According to the result of the comparison, the section 18 determines if they agree with each other or not.

If the two identification data do not agree with each other, the processing operation proceeds to Step  
20 S40, where it is determined that the interchangeable lens 110 is not properly matching. As a result, any operation of the camera is prohibited in Step S41 and the processing operation proceeds to Step S42, in which a predetermined damage routine is conducted. With this  
25 arrangement, the camera system does not work for any image pickup operation if an interchangeable lens 110 that does not match the camera body 30 is mounted on

the latter.

If, on the other hand, it is determined in Step S33 that no interchangeable lens 110 is mounted on the camera body 30 or the two identification data agree with each other in Step S39, the processing operation proceeds to Step S43. Then, the hardware-related information judging section 32 determines if the interchangeable lens 110 mounted on the camera body 30 is a matching one or not in a manner as described above by referring to the corresponding one of FIGS. 6 through 11.

If it is determined in Step S43 that the interchangeable lens 110 is not a matching one, the processing operation goes back to Step S40. If, on the other hand, it is determined that the interchangeable lens 110 is a matching one, the processing operation proceeds to Step S44.

In Step S43, it is determined if the interchangeable lens 110 mounted on the camera body 30 is properly matching or not. Subsequently, in Step S45, a proper sequence of operation is conducted for the camera.

Thereafter, a normal processing operation is conducted for the purpose of operating the camera. In this normal processing loop, if the interchangeable lens 110 is released from the camera body 30 or not is checked at regular time intervals by the lens mounting/releasing switch 22 in Step S46.

If it is determined that the interchangeable lens 110 is not released, the processing operation proceeds to Step S47, where it is determined if a command for checking the lens is issued by the user or not. If it is determined in Step S47 that a command for checking the lens is issued, the processing operation goes to Step S34 for a lens checking operation which is conducted in a manner as described above. On the other hand, if it is determined in Step S47 that no command is issued for checking the lens, a normal processing operation is conducted in Step S48. Then, the processing operation goes to Step S46 for the normal processing loop.

If it is detected by the lens mounting/releasing switch 22 in Step S46 that the interchangeable lens 110 is released from the camera body 30, the processing operation proceeds to Step S49. In Step S49, it is determined if an interchangeable lens 110 is mounted on the camera body 30 again or not.

If it is determined that an interchangeable lens 110 is mounted on the camera body 30 again, the processing operation goes back to Step S33. If, on the other hand, it is determined that no interchangeable lens 110 is mounted, the processing operation proceeds to Step S50 in order to deal with a situation where no interchangeable lens 110 is mounted. Thereafter, the processing operation returns to Step S49 and the

camera body waits for an interchangeable lens 110 to be mounted on it.

Now, the processing operation on the part of the interchangeable lens 110 will be described by referring  
5 to the flow chart of FIG. 13.

This processing operation is started when the interchangeable lens 110 is connected to the camera body 30.

As the processing operation starts, firstly the  
10 interchangeable lens 110 is initialized in Step S51. The initialization may typically include selection of a port. Then, in Step S52, the interchangeable lens 110 waits for a notification of a data communication to be conducted that is transmitted from the communicating  
15 section 12 of the camera body 30 and received by the communicating section 102.

Then, in Step S53, it is determined if the received notification of a data communication is for an identification data or not. If it is determined  
20 that the received notification is for an identification data, the processing operation proceeds to Step S54, where the group number transmitted from the camera body 30 in Step S35 is received and recognized.

Thereafter, in Step S55, Addresses X and Y of the  
25 identification data transmitted from the camera body 30 in Step S36 are received and recognized. Then, in Step S56, the recognized group number and Addresses X and Y

of the identification data are read out from the identification data storage section 16. Additionally, in Step S57, the read out identification data is transmitted back to the communicating section 12 of the camera body 30 from the communicating section 102.

If it is determined that the operation of Step S57 is terminated or the notification of a data communication is determined to be not for an identification data in Step S53, the ordinary processing operation for driving the lens is conducted in Step S58.

During the ordinary processing operation, it is determined in Step S59 if the camera body 30 requests a communication or not at regular time intervals. If it is determined that the camera body 30 requests a communication, the processing operation goes to Step S52 for the above described operation. If, on the other hand, it is determined that the camera body 30 does not request any communication, the ordinary processing loop is resumed.

Thus, the second embodiment of the invention is adapted to accurately recognize if the interchangeable lens mounted on the camera body is a properly matching one or not. Additionally, the camera system can be driven to operate only when a properly matching interchangeable lens that is accurately recognized to be as such is mounted on the camera body of the camera

system to remarkably improve the reliability of the entire camera system.

Now, the third and fourth embodiments of the present invention will be described below.

5           In each of the third and fourth embodiments of the invention, which will be described below, both the camera and the accessory have arithmetic expressions to be commonly used by them. More specifically, the data to be used for arithmetic operations including a  
10           plurality of numerical value data are prepared and transmitted to the accessory along with the data specified at the camera side and the outcome of the arithmetic operations performed at the accessory side on the basis of the data to be used for arithmetic  
15           operations is transmitted to the camera. If the outcome of the arithmetic operations performed by itself agrees with the outcome of the arithmetic operations performed by the accessory, the camera judges that the accessory is a right one. Therefore,  
20           it is possible to accurately judge if the accessory is a right one or not and prevent a fake accessory prepared by some other person from being illegally used with the camera.

          The data to be used for arithmetic operations may  
25           include a plurality of arithmetic expressions and predetermined arithmetic expressions may be selected from them and specified for use.

The third embodiment of the invention will be described below.

FIG. 14 is a functional block diagram of the third embodiment of the invention, which is a camera system, formed on the basis of the flow of signals to illustrate its configuration.

As shown in FIG. 14, the camera system comprises a camera body 150 and an interchangeable lens 170 that can be releasably mounted on the camera body 150 as accessory. The camera body 150 has a communication section 152 that can communicate with the interchangeable lens 170 for data communications, an arithmetic operations data outputting section 154, a camera side arithmetic section 156, a judging section 158, a control section 160 and a lens mounting/releasing switch (SW) 162.

On the other hand, the interchangeable lens 170 is an accessory that can be releasably mounted on the camera body 150. The interchangeable lens 170 has a communication section 172 that is adapted to communicate with the camera body 150 and a lens side arithmetic section 174. The fitting section of the camera body 150 and that of the interchangeable lens 170 are provided with respectively connection terminals 164, 176. When the camera body 150 and the interchangeable lens 170 are put together correctly, the connection terminal 164 and the connection terminal 176

contact each other so that the communication section 152 of the camera and the communication section 172 of the lens are electrically connected to each other.

5       The communication section 152 of the camera body 150 and the lens side communication section 172 are so adapted that the camera body 150 and the interchangeable lens 170 can mutually exchange data.

10       The arithmetic operations data outputting section 154 of the camera body 150 that outputs a plurality of numerical value data. The plurality of numerical value data is transmitted to the camera side arithmetic section 156 of the camera body 150. The plurality of numerical value data is also transmitted to the lens side arithmetic section 174 by way of the communication section 152 of the camera body 150 and the lens side communication section 172.

15       The camera side arithmetic section 156 in the camera body 150 and the lens side arithmetic section 174 store arithmetic expressions that are common to them. Predetermined arithmetic operations are performed, using the plurality of numerical value data that is transmitted to each of the arithmetic sections.

20       The outcome of the arithmetic operations performed by the camera side arithmetic section 156 is sent to the judging section 158 in the camera body 150. The outcome of the arithmetic operations performed by the lens side arithmetic section 174 is sent to the judging

section 158 in the camera body 150 by way of the lens side communication section 172 and the camera side communication section 152.

5       The judging section 158 in the camera body 150 compares the outcomes of the two arithmetic sections 156, 174. If they agree with each other as a result of the comparison, it is so judged that the mounted interchangeable lens is a right lens. The control section 160 in the camera body 150 controls the  
10       operation of the camera according to the result of judgment of the judging section 158.

      A lens mounting/releasing switch (SW) 162 that detects if the interchangeable lens 170 is mounted on or released from the camera body is connected to the  
15       control section 160. Thus, the control section 160 is notified of the timing of mounting the interchangeable lens 170 to and that of releasing the lens 170 from the camera body.

      Now, the data that is output from the arithmetic  
20       operations data outputting section 154 for arithmetic operations will be described below in detail along with the arithmetic operations.

      As shown in FIG. 15, the data to be used for an arithmetic operation include data of six numerical  
25       values. Of the data, the first data (data No. 1) indicates the data that is selected from the subsequent five data (data No. 2 through No. 6) so as to be

actually used for an arithmetic operation. In other words, only one of the five data is used for an arithmetic operation and all the remaining data are dummy data.

5           The arithmetic operation will be described further below with reference to FIG. 15 that shows an example.

Referring to FIG. 15, the first data "3" indicates the third one of the subsequent five data, or "9" of data No. 4. The six data of numerical values are  
10           output from a random number generating section (not shown) contained in the arithmetic operations data outputting section 154. Each time, the random number generating section outputs a data string that differs from any of the preceding data strings.

15           Both the camera side arithmetic section 156 in the camera body 150 and the lens side arithmetic section 174 perform respective arithmetic operations, using a common arithmetic expression. For the purpose of convenience, assume here that the arithmetic expression  
20           is

$$f(x) = ax + b \qquad \dots (1),$$

where x is the data to be used for the arithmetic operation and a and b are constants.

As pointed out above, if the interchangeable lens  
25           is a right lens, it stores arithmetic expressions that are common to the camera and the interchangeable lens. Therefore, the outcome of the arithmetic operation is

same for both the camera body and the interchangeable lens. However, since the arithmetic expressions and the data selection algorithm for selecting data to be used for arithmetic operation are not exposed to the  
5 manufacturer of the fake lens, the outcome of the arithmetic operation performed by the fake lens is not the same as the outcome of the arithmetic operation of the camera side arithmetic section 156. Therefore, the camera body judges that the interchangeable lens is not  
10 a right lens when the outcome of the arithmetic operation produced from the interchangeable lens is not the same as that of the arithmetic operation of the camera side arithmetic section 156.

When the camera side arithmetic section 156 and  
15 the lens side arithmetic section 174 receive the six data, they firstly refer to data No. 1 to extract the data to be used for the arithmetic operation.

Now, a digital single-lens reflex camera with interchangeable lenses realized by applying the present  
20 invention will be described below with reference to FIG. 16.

This camera system comprises as principal components a camera body 180 and a lens barrel 190 that correspond respectively to the camera body 150 and the  
25 interchangeable lens 170 shown in FIG. 14. A desired lens barrel 190 can be releasably fitted to the front surface of the camera body 180.

The lens barrel 190 is controlled by a lens control microcomputer (to be referred to as Lucom hereinafter) 192, which Lucom 192 includes the communication section 172 and the lens side arithmetic section 174 of FIG. 14.

The camera body 180 is controlled by a body control microcomputer (to be referred to as Bucom hereinafter) 210, which Bucom 210 includes the communication section 152, the arithmetic operations data outputting section 154, the camera side arithmetic section 156, the judging section 158 and the a control section 160 of FIG. 14.

Lucom 192 and Bucom 210 are electrically connected to each other by way of a communication connector 206 at the time of putting them together so that they can communicate with each other. The communication connector 206 corresponds to the connection terminals 164 and 176 of FIG. 14.

In the camera system, Lucom 192 cooperates with Bucom 210 as subordinate.

An imaging optical system 194 and a diaphragm 196 are arranged in the lens barrel 190. The imaging optical system 194 is driven by a DC motor (not shown) arranged in lens drive mechanism 198. The diaphragm 196 is driven by a stepping motor (not shown) arranged in a diaphragm drive mechanism 200.

Lucom 192 controls these motors according to the

commands issued from Bpcom 210.

The camera body 180 contains therein the following components in a manner as schematically illustrated in FIG. 16.

5           The components typically include optical components required for a single-lens reflex camera (a reflector 212, a sub-mirror 214, a pentaprism 216 and an eyepiece 218). The camera body 180 also contains therein a focal plane type shutter 220 arranged on  
10           the optical axis thereof and an AF sensor unit 222 that automatically focuses on the object to be shot upon receiving the flux of light reflected by the sub-mirror 214.

          The camera body 180 additionally contains therein  
15           an AF sensor drive circuit 224 that drives and controls the AF sensor unit 222, a mirror drive mechanism 226 that drives and controls the reflector 212, a shutter charging mechanism 228 that charges the spring for driving the front curtain and the rear curtain of the  
20           shutter 220 with resilient force, a shutter control circuit 230 that controls the movement of the front curtain and that of the rear curtain and a photometric circuit 232 that operates for photometric on the basis of the flux of light from the pentaprism 216.

25           An imaging device 234 that is a photoelectric conversion device for photoelectrically converting the image of the object that is picked up and made to pass

through the imaging optical system is arranged on the optical axis.

The camera system further comprises an interface circuit 236 connected to the imaging device 234, a liquid crystal monitor 238 and an image processing controller 246 that processes images by utilizing an SDRAM 240, a flash ROM 242, a recording medium 244 and the like that are provided as storage regions so that it has electronically recording/displaying functional features as well as electronically imaging functional features.

A non-volatile memory 248 that is typically an EEPROM and can be accessed from Bpcom 210 is provided as non-volatile memory means in order to store predetermined control parameters that are necessary for controlling the camera.

The Bpcom 210 comprises an operation display LCD 250 for notifying the user of the operating status of the camera by means of a display output, a camera operation switch (SW) 252, a battery 254 that operates as power source and a power supply circuit 256.

The camera operation switch 252 is provided as a group of switches that typically include a release switch, a mode-shifting switch and a power switch that are necessary for operating the camera. Many of the switches are realized in the form of operation buttons. The power supply circuit 256 is provided in order to

change the voltage of the battery 254 operating as power source to the voltages that are required by the circuit units of the camera system. The above listed components of the camera system having the above  
5 described configuration operate in a manner as described below.

The image processing controller 246 controls the interface circuit 236 so as to take in the image data of the imaging device 234 according to the command  
10 issued from the Bpcom 210. The image data is then converted into a video signal by the image processing controller 246 and output to and displayed on the liquid crystal monitor 238. The user can confirm the picked up image by seeing the image displayed on the  
15 liquid crystal monitor 238.

The SDRAM 240 is a memory for temporarily storing the image data. It is used as a work area for the operation of converting the image data. The image data is also converted into a JPEG data and stored in the  
20 recording medium 244.

The mirror drive mechanism 226 is adapted to drive the reflector 212 either to an UP position or to a DOWN position. When the reflector 212 is at the DOWN position, the flux of light entering through the  
25 imaging optical system 194 is divided into a flux of light that is led to the AF sensor unit 222 and a flux of light that is led to the pentaprism 216.

The output from the AF sensor in the AF sensor unit 222 is transmitted to the Bucom 210 by way of the AF sensor drive circuit 224. With this arrangement, an operation of measuring the distance is performed in a known manner.

The user can visually observe an image of the object to be shot through the eyepiece 218 located adjacent to the pentaprism 216. The flux of light passing through the pentaprism 216 is partly led to a photo sensor (not shown) arranged in the photometric circuit 232 so that a photometric operation is performed on the basis of the detected quantity of light in a known manner.

Now, the operation of the camera body 180 will be described below with reference to FIG. 17.

FIG. 17 is a flow chart illustrating the sequence of operation of the camera body 180.

The illustrated sequence of operation starts as the camera body 180 is powered by the power source. Then, firstly in Step S61, the camera is initialized in an ordinary manner so that a necessary port may be selected. Then, in Step S62, it is determined if the lens barrel 190 is fitted to the camera body 180 or not. This operation is performed by means of a detection signal from the camera operation switch 252 that includes a lens mounting/releasing switch 162.

If the lens barrel 190 is not fitted to the camera

body 180, the operation sequence proceeds to Step S63, where a processing operation for a no lens situation is performed. Subsequently, the operation sequence moves to Step S62.

5           If, on the other hand, it is found in Step S62 that the lens barrel 190 is fitted to the camera body 180, the operation sequence proceeds to Step S64, where it is determined if the lens barrel 190 is newly fitted to the camera body 180 (and hence a lens changing  
10           operation has been performed) or it has been fitted for sometime. If it is determined that the lens barrel 190 is newly fitted to the camera body 180, the lens identification process from Step S65 is started. If, on the other hand, it is determined that the lens  
15           barrel 190 has been fitted to the camera body 180 for sometime, the operation sequence proceeds to Step S74.

          In Step S65, the data to be used for arithmetic operations are output from the arithmetic operations data outputting section 154 in the camera body 180.  
20           Then, in Step S66, the data to be used for arithmetic operations output in Step S65 are transmitted to the lens barrel 190 from the camera body 180.

          In Step S67, predetermined arithmetic operations are performed by using the data to be used for the  
25           operations. Note that arithmetic operations similar to those of Step S67 are performed also in Lpcom 192 of the lens barrel 190.

In Step S68, the outcome of the arithmetic operations that are performed by using the data transmitted in Step S66 is then transmitted from the lens barrel 190. Then, the outcome of the arithmetic operations is assessed in Step S69. In other words, the outcome of the arithmetic operations performed by the camera side arithmetic section 156 in the camera body 180 and that of the arithmetic operations transmitted from the lens barrel 190 and received in Step S68 are compared.

Then, in Step S70, it is determined if the two outcomes agree with each other or not. If the two outcomes do not agree with each other as a result of the comparison, the operation sequence proceeds to Step S71, where the lens is judged to be NG. Thus, any subsequent operations are prohibited in the next Step S72. Subsequently, the operation sequence proceeds to Step S73, where a damage operation is performed to prohibit any operations that may be performed at the user side.

Alternatively, only operations relating to the lens barrel 190 may be prohibited.

If, on the other hand, it is found in Step S70 that the two outcomes agree with each other, the operation sequence proceeds to Step S74, where the lens is judged to be OK. Thus, normal operations (including shooting operations) are allowed to be performed by the

camera in the next Step S75.

In the next Step S76, it is determined if the lens barrel 190 is released or not. The operation sequence proceeds to Step S62 if it is found that the lens  
5 barrel 190 is released from the camera body 180, whereas the operation goes to Step S77 if it is found that the lens barrel 190 is not released from the camera body 180.

In Step S77, it is determined if a processing  
10 operation of identifying the lens barrel 190 is to be performed or not. This processing operation of identifying the lens barrel 190 is triggered by a user operation of turning on the power switch, the release switch or the like. The operation sequence moves back  
15 to Step S65 to perform the processing operations of the subsequent steps if it is determined that the processing operation of identifying the lens barrel 190 is to be performed.

If, on the other hand, it is determined that the  
20 processing operation of identifying the lens barrel 190 is not to be performed, the operation sequence proceeds to Step S75, where an ordinary processing operation is performed. Then, the operation sequence proceeds to Step S76, where the loop of ordinary processing  
25 operations is repeated except when it is determined that the lens is to be released and checked in Steps S76 and S77 respectively.

When Lpcom 192 of the lens barrel 190 receives six numerical values from the camera body 180 in response to the above described processing operation in Step S66, it selects the data to be used for the  
5 predetermined arithmetic operation out of the numerical values. Then, the predetermined arithmetic operation is performed by using the selected data and the outcome of the arithmetic operation is transmitted to the camera body 180.

10 As for the data selection, a numerical value is selected from five numerical values according to the remaining numerical value (the first numerical value), the five numerical values being the second through sixth numerical values.

15 Now, the fourth embodiment of the invention will be described below.

FIG. 18 is a functional block diagram of the fourth embodiment of the invention, which is a camera system, formed on the basis of the flow of signals to  
20 illustrate its configuration.

In FIG. 18, the components same as or similar to those of the third embodiment illustrated in FIG. 14 are denoted respectively by the same reference symbols and will not be described any further. In other words,  
25 only the components that are different from the third embodiment will be described below.

While both the camera side and the lens side are

provided with only a single arithmetic expression in the above described third embodiment, the fourth embodiment differs from the third embodiment in that the camera side and the lens side are provided with a plurality of arithmetic expressions in the fourth embodiment.

More specifically, the camera side arithmetic section 156 has a camera side arithmetic expressions storage section 166 that stores a plurality of arithmetic expressions. On the other hand, the lens side arithmetic section 174 has a lens side arithmetic expressions storage section 178 that stores the arithmetic expressions same as those stored in the camera side arithmetic expressions storage section 166. Therefore, the plural numerical values output from the arithmetic operations data outputting section 154 outputs data to be used for arithmetic operations include a data for specifying one of the arithmetic expressions.

This will be described further with reference to FIG. 19 that illustrates an example.

To begin with, assume that the camera side arithmetic expressions storage section 166 and the lens side arithmetic expressions storage section 178 store the following three arithmetic expressions (2), (3) and (4) that are common to them;

$$f(x) = ax + b \quad \dots (2),$$

$$f(x) = cx + d \quad \dots (3) \text{ and}$$

$$f(x) = ex + f \quad \dots (4),$$

where x is the data to be used for the selected arithmetic operation and a, b, c, d, e and f are constants.

The data to be used to the selected arithmetic operation that are output from the arithmetic operations data outputting section 154 include the first through seventh numerical values. The first numerical value (data No. 1) is used to specify the arithmetic expression out of the plurality of numerical expressions stored in the camera side arithmetic expressions storage section 166 and the lens side arithmetic expressions storage section 176.

The next numerical value (data No. 2) is used to specify the numerical value out of the subsequent five numerical values (data No. 3 through No. 7) so as to be actually used for an arithmetic operation as in the case of the third embodiment.

Referring to FIG. 19, the first data "3" indicates the third one of the arithmetic expressions is to be used and the second data "2" indicates the second one of the subsequent five data, or data No. 4 "9" is to be used for the x in the arithmetic expression.

On the other hand, upon receiving the seven data from the camera body, Lpcom 192 of the lens barrel 190 selects the arithmetic expression to be used according

to the first data of the seven data and then selects  
the data to be used for the x in the selected  
arithmetic expressions out of the remaining data  
according to the second data of the seven data. Then,  
5 it performs an arithmetic operation, using the selected  
arithmetic expression and the selected numerical value  
and transmits the outcome of the arithmetic operation  
to the camera body.

With the above described arrangement, it is  
10 possible to rigorously recognize if the interchangeable  
lens mounted to the camera body is a right one or a  
wrong one.

While the first and fourth embodiments are  
described above in terms of an interchangeable lens as  
15 accessory, the present invention is equally applicable  
to other accessories such as a flash unit and a battery  
pack to provide similar advantages.

Thus, as described above in detail, the present  
invention provides a camera system comprising a camera  
20 body that can recognize if the accessory mounted on it  
is a valid one or a fake one.

Additionally, as described above in detail, the  
present invention provides a camera comprising a camera  
body that can recognize if the accessory mounted on it  
25 is a valid one or a fake one.

Furthermore, as described in detail, the present  
invention provides a method of judging and controlling

an accessory, with which a camera body can recognize if the accessory mounted it is a valid one or a fake one.

Additional advantages and modifications will readily occur to those skilled in the art. Therefore, 5 the invention in its broader aspects is not limited to the specific details and representative embodiments shown and described herein. Accordingly, various modifications may be made without departing from the spirit or scope of the general inventive concept as 10 defined by the appended claims and their equivalents.
